# The collections module

- Part of Python's Standard Library (built-in module)
- Specialized container datatypes
  - Alternatives to general purpose dict, list, set, and tuple
- Notable:
  - `namedtuple` : tuple subclasses with named fields
  - `deque` : list-like container with fast appends and pops
  - `Counter` : dict for counting hashable objects
  - `OrderedDict` : dict that retains order of entries
  - `defaultdict` : dict that calls a factory function to supply missing values

Engineering Consultants

# Set theory

- Branch of Mathematics applied to collections of objects
  - i.e., sets
- Python has built-in set datatype with accompanying methods:
  - intersection() : all elements that are in both sets
  - difference() : all elements in one set but not the other
  - symmetric\_difference() : all elements in exactly one set
  - union() : all elements that are in either set
- Fast membership testing
  - Check if a value exists in a sequence or not
  - Using the in operator

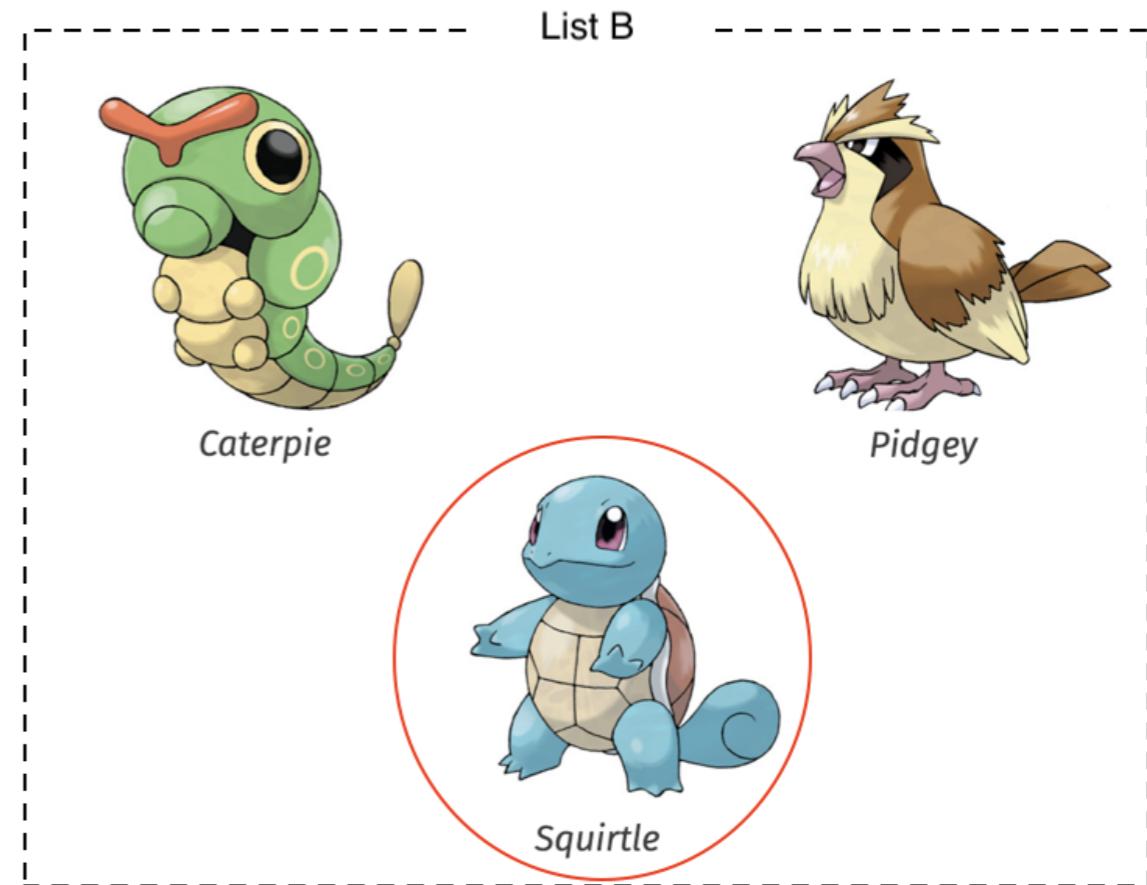

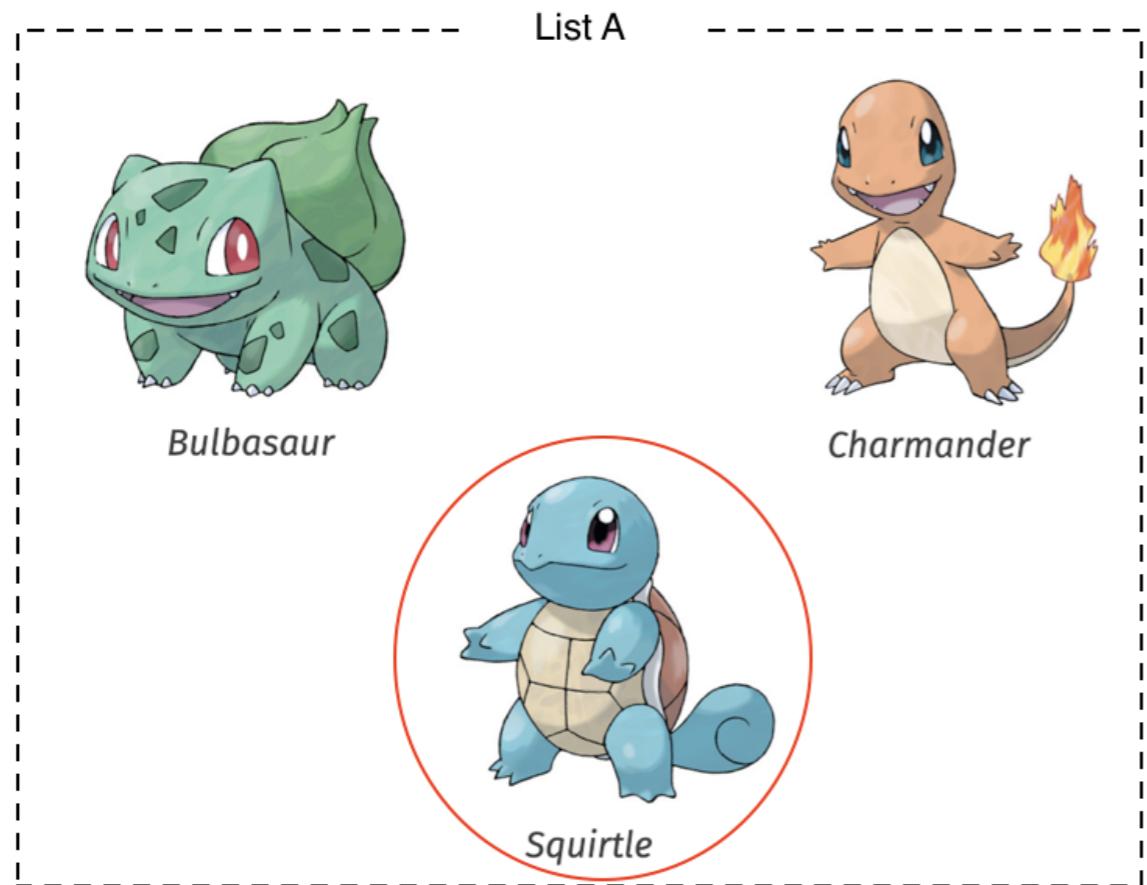

# Comparing objects with loops

```
list_a = ['Bulbasaur', 'Charmander', 'Squirtle']  
list_b = ['Caterpie', 'Pidgey', 'Squirtle']
```

# Comparing objects with loops

WRITING EFFICIENT PYTHON CODE

# Eliminating loops

WRITING EFFICIENT PYTHON CODE

Logan Thomas

Senior Data Scientist, Protection  
Engineering Consultants

# Looping in Python

- Looping patterns:
  - `for` loop: iterate over sequence piece-by-piece
  - `while` loop: repeat loop as long as condition is met
  - "nested" loops: use one loop inside another loop
  - Costly!

# Benefits of eliminating loops

- Fewer lines of code
- Better code readability
  - "Flat is better than nested"
- Efficiency gains

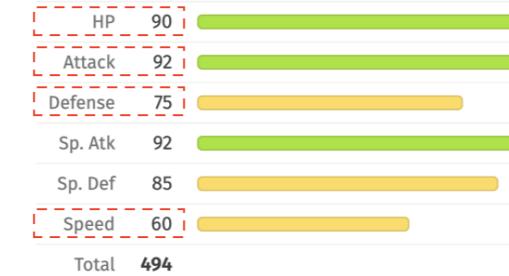

# Eliminating loops with built-ins

```
# List of HP, Attack, Defense, Speed

# Lesson caveat

- Some of the following loops can be eliminated with techniques covered in previous lessons.
- Examples in this lesson are used for **demonstrative** purposes.

**Warning:** *For demonstration purposes only*

# Writing better loops

- Understand what is being done with each loop iteration
- Move one-time calculations outside (above) the loop
- Use holistic conversions outside (below) the loop
- Anything that is done **once** should be outside the loop

# Moving calculations above a loop

```
import numpy as np

names = ['Absol', 'Aron', 'Jynx', 'Natu', 'Onix']
attacks = np.array([130, 70, 50, 50, 45])

for pokemon, attack in zip(names, attacks):
    total_attack_avg = attacks.mean()
    if attack > total_attack_avg:
        print(
            "{}'s attack: {} > average: {}!".format(pokemon, attack, total_attack_avg)
        )
```

```
Absol's attack: 130 > average: 69.0!
Aron's attack: 70 > average: 69.0!
```

```
import numpy as np

names = ['Absol', 'Aron', 'Jynx', 'Natu', 'Onix']
attacks = np.array([130, 70, 50, 50, 45])
# Calculate total average once (outside the loop)
total_attack_avg = attacks.mean()

for pokemon, attack in zip(names, attacks):

    if attack > total_attack_avg:
        print(
